

(a) Interaction $I = E_L - E_J$ under each ablation

circles: the per-category values behind each mean

(b) Absolute localisation the same ablations move

Exploratory: the E2 table holds seed 0 and $K = 1$ only, one run per ablation, so no interval exists and none is drawn. ABL-S removes the Gaussian smoothing, ABL-C replaces score fusion with naive concatenation ($\alpha = w$ for equal slots, so only BAL can move), ABL-N removes per-branch normalisation and scores with squared Euclidean distance.
